4.2.2 Symbology of vector layers

When you add a vector layer, QGIS shows it with a random colour, unless a style is stored with the data. In both cases, you can easily adapt its appearance to your needs.

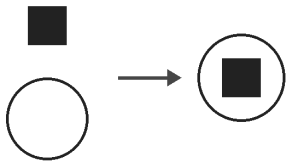

You set the symbology per layer, so **each layer can have its own style**. You do this in the *Layer Properties* (see The Layer Properties window).

In the *Symbology* tab you decide how the layer is displayed on the map. At the top (A) you choose the type of symbology: *Single Symbol* displays all features in the same way, while other types give features a different style depending on their attribute values (see, for example, One style per category). At B you see which parts, or *symbol layers*, your symbol is made of. In this part of the window you can add and remove symbol layers and change their order. Selecting a symbol layer here opens its more detailed settings in the lower part of the window.

Tip

Often a symbol consists of a single symbol layer, but combining several symbol layers gives you a lot of freedom. Suppose you want a black square inside a white circle, for example to mark capital cities. There is no ready-made symbol for that, but there are ready-made symbols for a circle and for a square. So you can easily compile the desired marker yourself: make a first symbol layer with a white circle, then a second symbol layer with a smaller black square, and place the square on top of the circle. See Symbols with several layers.

At C you set the basic properties of your symbol, such as its size, colour and opacity. QGIS also offers a list of predefined symbols that you can choose from.

Points, lines and polygons each have their own characteristics, so the styling options differ a little between them: points are displayed with a marker (a symbol or icon), lines with a line style and polygons with a fill. On the whole, however, the configuration works in the same way and the available options are very similar.
